

# SMART LAPTOP REQUEST MANAGEMENT

---

## 1. Ideation

The Smart Laptop Request Management project was conceived to address the inefficiencies associated with manual laptop allocation processes within organizations. In many companies, employees request laptops through emails, phone calls, or informal communication channels, making it difficult for the IT department to track requests, monitor approvals, and maintain accurate records. This often results in delayed approvals, lack of transparency, duplicate requests, and increased administrative effort.

To overcome these challenges, an automated solution was proposed using the ServiceNow platform. The idea was to design a self-service application that allows employees to submit laptop requests through an intuitive catalog interface. The application should enable managers to review and approve requests, automatically create tasks for the IT team, and notify stakeholders about the progress of the request. By digitizing the entire process, the organization can significantly reduce manual intervention and ensure that all requests are processed consistently and efficiently.

The proposed system aims to provide employees with a seamless experience while giving administrators complete visibility into the request lifecycle. It also establishes a centralized repository where all request information can be stored for future reference, reporting, and auditing purposes. The project aligns with the organization's goal of improving operational efficiency through workflow automation and self-service capabilities.

Several ideas were explored during the ideation phase, including integration with asset management systems, inventory tracking, and predictive analytics for estimating laptop demand. However, considering the scope and timeline of the project, the focus was narrowed to developing a fully functional laptop request workflow that demonstrates the core capabilities of ServiceNow, including Service Catalog, Flow Designer, approvals, and notifications.
